RESEARCH ARTICLE CLASS PROJECT

Lifespan is Effected by Sex and Marital Status

Brandon Thomas Hendrickson[1,*]

Abstract

Purpose: This project describes lifespan patterns in cemetery records and examines variation by sex and marital status. [you can do military service of males or pre- and post- a particular year - default 1930]

Methods: Recorded available birth and death information from gravestones and classified selected characteristics using evidence visible on the stones and in burial arrangements. [Go into much greater detail in the methods section]

Results: [Summarize the principal patterns in the class data.]

Conclusions: [State what the observed patterns suggest and note limitations. Distinguish lifespan in this cemetery sample from population life expectancy.]

Keywords: cemetery records; lifespan; survivorship; marital status; historical demography

Background

Cemetery records provide individual birth and death dates that can be used to describe lifespan among people represented in a burial ground. These records are a non-random sample: cemetery access, preservation of markers, migration, family burial practices, and the choice of graves to record may all affect which people appear in the dataset. The analyses below therefore describe the collected sample and should not be treated as direct estimates of lifespan for an entire town or historical population.

Hypotheses

3. **Military service and lifespan:** I hypothesize that male records marked as military service will show lower lifespan than records not marked for service because of drafting, exposure to chemical agents, and the dangers associated with military lifestyle.

Methods

Field site and sampling

- **Where did you go?** We went to the Sunset Hills Cemetary in Valdosta, Georgia located next to the VSU campus. We stayed around the southeastern end of the cemetary and wrote down names on the headstones.
- **What date and time of day did you collect records?** We went on Thursday October 8th, 2026, from around 2:15 PM to around 3:00 PM.
- **What part of the cemetery did you sample?** I stayed around the southeastern part of the cemetary.
- **How did you choose graves?** We chose gravestones at random initially, but then went along down the rows, only skipping over the gravestones that were illegible.
- **How did you handle nearby graves and family plots?** I wrote down names next to each other if they were part of the same family, keeping them together before moving onto another last name.

Recorded information and variable definitions

- **What information did you record from each marker?** I recorded names, birth date, death date, gender, and military status.
- **How was lifespan calculated?** I calculated the lifespan by subtracting the death year by the birth year and then determined if they passed before or after their birthday within the year.
- **How did you determine marital status?** I did not record marital status in my data due to being unable to determine from the data the gravestones provided. [Explain evidence such as "wife," "husband," spouse names, or paired markers. If a joint grave was used as evidence, state that this is an inference and describe the rule.]
- **How did you determine military service?** The gravestones stated whether or not the deceased individual was a veteran along with their rank. Those that didn't state the individual was a veteran, I assumed they were not in the military. [Describe explicit evidence such as service branch, rank, unit, or veteran symbols. Explain how uncertain cases were coded.]
- **How did you determine sex or gender?** I determined the gender of the individual based on their names and if they had a masculine or feminine name. [Describe what was explicitly recorded and what, if anything, was inferred. Do not present an inference as a confirmed identity.]
- **How were missing, illegible, or ambiguous records handled?** I skipped over the greavestones with illegible or missing data and did not record them. [State exclusion and coding rules.]

Dataset and analysis

- **How many records were collected by you?** n = 25 [n =]
- **How many records were included in the final analysis?** [n = ; explain exclusions.]
- **Were records aggregated with the class dataset?** [Yes / no. If yes, describe how duplicates and conflicting entries were checked.]
- **What summaries or plots were produced?** [Describe group summaries and empirical survivorship curves, including how categories were defined.]
- **What are the limits of the sample?** [Discuss marker preservation, incomplete dates, cemetery selection, sampling strategy, and any other relevant limitations.]

Results

Replace each image placeholder with a PNG of the matching plot from the final class dataset. Keep figures in the `survivorship_curves` and `cemetery_lifespan_report_files` folder, or update the image path in the Markdown. The figure captions are editable and should describe the plotted groups, axes, and relevant reference lines.

Summarize the data both by referencing Figure 1 and by writing out what the table is displaying specific to your particular research hypothesis. For instance, if you are interested only in marriage status and sex, then report the mean and standard deviation of males and females that are married vs unmarried; you do not need to discuss military status unless this is part of your research question/hypothesis.

The summary table in Figure 1 shows substantial differences in recorded lifespan by sex in this sample. Males had a mean lifespan of 59.0 years (SD = 20.4; n = 3), compared with 29.7 years (SD = 7.1; n = 3) for females. The marital-status breakdown is more tentative because each subgroup contains only one or two records. Among males, the two married individuals had a mean lifespan of 70.5 years (SD = 6.4), while the one unmarried individual lived 36 years. Among females, the one married individual lived 36 years, compared with a mean of 26.5 years (SD = 6.4) for the two unmarried individuals. These small subgroup sizes make the values descriptive; they do not support broad conclusions about sex or marital status.

The sex-specific survivorship curves in Figure 2 show a different pattern: the plotted means are 61.1 years for males and 57.3 years for females. The male curve remains higher through much of the earlier and middle lifespan, while the female curve reaches the 50% survival point later. The curves

Lifespan by sex

Sex	n	Mean	SD	Median	Minimum	Maximum
f	342	71.1	21.9	76	0	105
m	410	62.2	23.0	67	0	114

Lifespan by sex and marital status

Sex	Married	n	Mean	SD	Median	Minimum	Maximum
f	n	164	69.0	25.9	76	0	105
f	y	178	73.2	17.2	77	16	101
m	n	240	57.8	25.8	64	0	97
m	y	170	68.5	16.4	71	25	114

Figure 1: Summary of lifespan by sex and by marrital status for each sex.

are close and change relative position, so the figure suggests that the sex difference depends on which part of the lifespan distribution is considered. The median markers indicate where each group's observed curve reaches 50% surviving; they are distinct from the mean values shown in the legend.

The within-sex comparisons in Figure 3 show higher plotted mean lifespans for married than unmarried individuals in both panels. For males, the plotted means are 64.3 years for married individuals and 55.4 years for unmarried individuals. For females, they are 64.3 and 46.3 years, respectively. The curves also place the 50% survival point later for the married groups. These are descriptive differences and should not be interpreted as evidence that marriage caused longer lifespan; other factors and the sizes and composition of the groups could contribute.

Summary of observed results: [Describe the main pattern, sample size for each comparison, and any uncertainty or missing-data issue. Refer to the figures by number. Do not infer causation from group differences.]

Discussion

Write a paragraph or two, citing your sources to prove the results of your data. **Sex and lifespan.** Research on sex differences in longevity points to a combination of biological, behavioral, and social influences rather than a single explanation. Austad and Fischer review evidence on sex differences in lifespan and aging across species, including humans (Austad & Fischer, 2016). In this cemetery sample, the observed female and male curves [describe the pattern] and [support / do not support] the prediction that [state your hypothesis]. The result should be interpreted in the context of this cemetery's birth cohorts and sampling process; it is not by itself an estimate of a general sex difference in lifespan.

Marital status and social relationships. Marriage can correlate with social support, health behaviors, household resources, and social integration, but people's health can also influence whether they marry or remain married. A large meta-analysis found associations between unmarried status and mortality, with some associations differing by sex (Wang *et al.*, 2020); a broader meta-analysis linked social relationships with mortality risk (Holt-Lunstad *et al.*, 2010). In this dataset, the comparison of married and not-married records among [men / women / both] showed [describe results]. These cemetery records do not measure relationship quality, social contact, or the timing and duration of marriage, so marital status should be treated as an imperfect indicator rather than a direct measure of socialization or a cause of longevity.

Historical changes in lifespan and childhood survival. Life expectancy at birth is strongly affected by deaths in infancy and childhood, so a low historical average does not mean that every adult died young. Improvements in clean water and sanitation contributed substantially to mortality declines in the United States during the twentieth century, especially for infants and children (Cutler & Miller, 2005). The birth-period pattern in this sample [describe results] may be

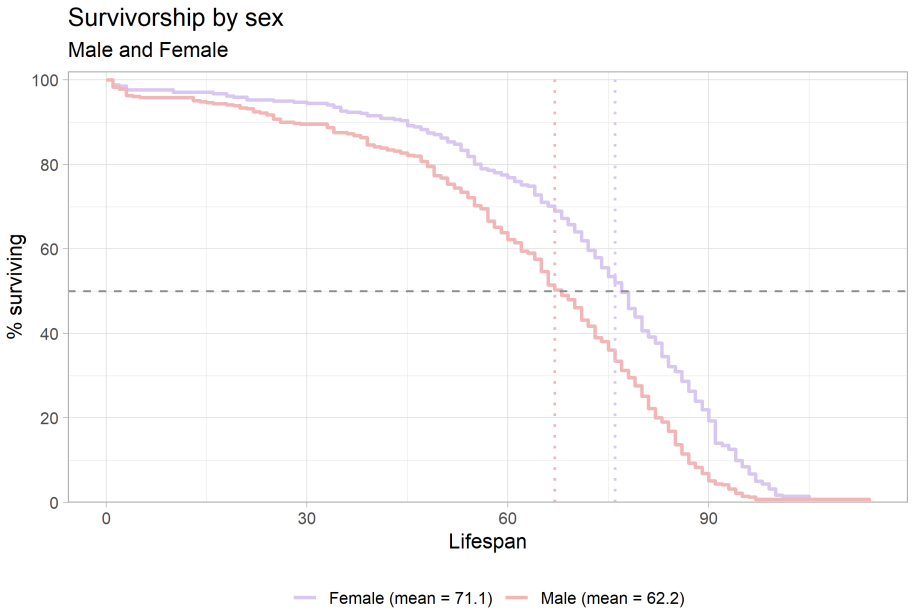

Figure 2: Survivorship curves by sex. The y-axis shows the percentage of the cemetery sample surviving to each lifespan. Dotted vertical lines mark the median lifespan for each sex, where the curve reaches 50%.

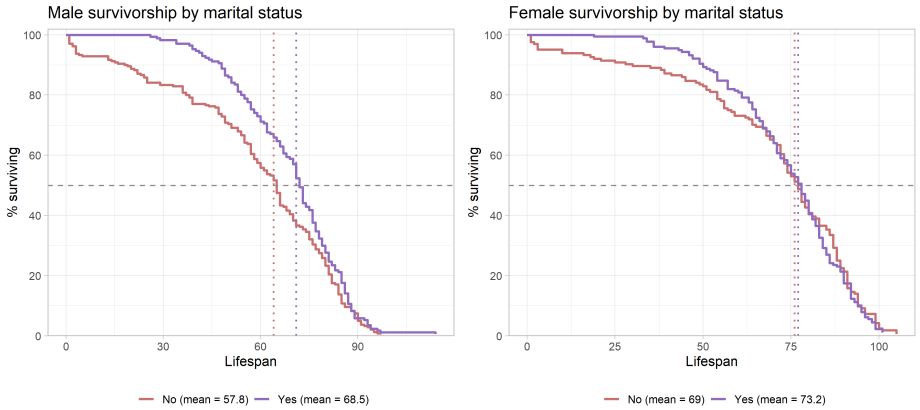

Figure 3: Survivorship by marital status, with separate male and female panels. Dotted vertical lines mark the median lifespan for each marital-status group, where the curve reaches 50%.

consistent with changing survival conditions, but birth year alone cannot identify which changes mattered. Vaccination, nutrition, medical care, living conditions, and the incomplete representation of people in cemetery records may also contribute to differences across cohorts.

Limitations and next steps: [Discuss sample size, missing or inferred data, cemetery representation, family clustering, survivorship bias, and what additional evidence would strengthen the analysis.]
